⑤④ Moisture-resistant cable splice and sealing structure thereof.

⑤⑦ A protective enclosure for use with one or more electric cables (10, 12) comprises first and second elongate casings (16, 18) juxtaposed along respective end surfaces thereof to define a housing with an open interior, at least one electrical cable (10, 12) disposed in the housing interior in an encapsulant, the encapsulating filling the housing interior. At least one end closure (20, 22) is disposed in the housing and defines a cable passage therethrough, the cable being resident in part in the cable passage. Seal-effecting structure for providing sealed relations (16a, 18a, 18b, 28) between the end closure and the first and second casings (24, 26) inclusive of a cover plate disposed in confronting relation to the end closure and movable relative thereto.

FIELD OF THE INVENTION

This invention relates generally to protectively enclosing spliced or terminated electrical cables and pertains more particularly to moisture-resistant cable connections.

BACKGROUND OF THE INVENTION

Telecommunication cables are typically provided outdoors either overhead or buried in the ground. When splices to these cables must be effected, either for repair or further interconnection purposes, the spliced area (splice) must be protected against the environment.

A fully protected multiple conductor cable splice often has a protective casing which may be opened for splice purposes, newly-made connections or repair of prior connections. Closure of the casing subjects the cables again to moisture intrusion. Moisture which bridges connections or exposed conductors gives rise to faults which disrupt or otherwise undermine intended communication channels, requiring costly reopening of the spliced connection, trouble-shooting and correction thereof. Moisture susceptibility is heightened where the spliced connection is located underground or in another high moisture environment.

The prior art is replete with varied approaches to a solution of the moisture intrusion problem, generally falling into three categories.

In a first type of approach, the art has looked to the application of an electrically insulative fluid to the individual conductors and connections, the fluid being of a type which "sets" or generally solidifies within the passage of time, i.e., an encapsulant. In the interval between application and setting of the fluid, mechanical force is applied thereto to induce movement of the fluid fully into the interstices between the conductors and connections. In this first approach, the mechanical force is provided by pressure-wrapping a tape member over the fluid, with successive courses of the wrapping overlapping prior courses of the wrapping and with successive longitudinal wrappings often being applied. In a variation of this first type of approach, a flexible bag is configured over the cable length to be protected with the fluid being introduced by pouring it into the bag. The open portion of the bag is then folded over the remnant thereof and the tape member is applied to the bag. In either instance, a non-rigid outer enclosure is applied to the tape wrap and sealingly secured to the cable outwardly of the splice and, at times, also to the tape wrap.

While the described practice has been successfully implemented, applicability thereof has limitations. Thus, it is not useful in installations in which the completed splice is likely to be subject to mechanical force beyond that tolerable by the non-rigid outer enclosure.

SUMMARY OF THE INVENTION

The second approach involves the steps of the first approach through the tape wrapping step. Following that juncture, however, this approach departs in providing a rigid enclosure for the splice, typically in the form of a pair of mated semi-cylindrical shells sealably secured to one another and to end plates applied to the cables prior to making the splice. In a variation of practice in the second approach, the mechanical force to displace the fluid into the splice interstices, while derived in part from the wrapping, is derived in further part by interiorly pressurizing the rigid enclosure after sealing has been effected.

The second approach, while providing an assembly suited for the environments not met by the first approach, is evidently as labor intensive in requiring the wrapping practice, and further involves the additional step of pressurization of the wrapped subassembly. In a third approach, the art has looked to the introduction of the encapsulating fluid under pressure within a rigid enclosure. This approach omits the wrapping step following the splicing. Rigid semi-cylindrical housings are applied and are sealingly joined to one another as in the second approach. The enclosure thus formed defines an inlet port to which a caulking gun type of device containing the encapsulant fluid is connected. The enclosure further defines a closed outlet port in which is seated a pop-up type pressure indicator. In the course of a user pumping the fluid into the enclosure, by repetitively refilling the caulking gun from a bulk container of the encapsulant fluid, a point in time is reached when the pressure indicator is activated and the assembly is then considered complete.

The third approach is seen as advantageous in its provision of both a rigid enclosure and in the introduction of the encapsulating fluid under pressure, with attendant likelihood of lessening voids, e.g., entrapped air bubbles possibly receptive of moisture. However, disadvantage is seen in the use of a closed outlet while pumping fluid into the enclosure under pressure. While air may escape before the outlet is closed, some air may remain in the enclosure which may mix with the encapsulant fluid to cause air pockets or bubbles in the fluid. Further, the described practice is seen as unduly labor-intensive and time-consuming in its requirement for repetitive retreat to the bulk encapsulant container. Still further, known sealing measures and structures in the prior art in respect of this third approach are seen as less efficacious than needed for satisfaction of industry demand.

A primary object of the present invention is the provision of improved protection of spliced electrical cables over the known techniques.

surfaces 16 and 18 looking toward end plate assembly

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS AND PRACTICES

Referred to Fig. 1, multiconductor cables 10 and

12 have respective insulative jackets 10a and 12a from which extend insulated conductors 10b and 12b to be spliced together. Connection of conductors 10b and 12b, although not shown, may be achieved by conventional techniques to form cable splices, taps or repairs, the term splice as used herein encompassing the joining of conductors in the same or different cables. Various components of the kit 14 of parts for

use in protectively enclosing the electrical cables to be spliced together are shown in exploded manner.

First and second elongate casings, i.e., top closure 16 and bottom closure 18, are comprised of rigid

plastic material. Each casing defines a hollow interior with open sides and ends. The ends are closable by

end plate assemblies 20 and 22 and end plate assembly seals 24 and 26.

pumped directly from container 44 into the assembly. Pump 40 may be a commercially-available product, such as a hand operated, self-priming pump.

At this stage, it should be pointed out that valves 36 are conventional pressure relief valves that may be preset by the manufacturer to open to provide pressure relief at a predetermined pressure. It has been determined that for the present technique, a pressure of approximately 15 psig is sufficient to provide the desired sealing effect. However, the operating pressure range has been found to be between 12 and 18 psig, although other pressure ranges for different applications may also be considered. Accordingly, the pressure relief valves for use in the instant method are preset at a pressure of about 15 psig. Two valves 36 are used, as illustrated in Fig. 20, at both ends of the top closure 16. It is desirable to orient the relief valve at a location higher than the fitting 38 through which the encapsulant fluid is pumped into the enclosure. The use of one valve 36 at each end of the enclosure thus allows the fluid pumping to proceed with at least one of such valves 36 being higher than the fitting 38 despite enclosure orientation.

Fitting 38, which is connected to the pump hose 42, is a conventional check valve that allows fluid entry but as the pressure increases internally, the valve closes, thereby preventing backflow of fluid or air out through the valve.

In the course of the pumping of the encapsulant fluid into the enclosure under pressure, any trapped air, as well as the entering encapsulant, are compressed within the enclosure under pressure. When the pressure within the enclosure reaches 15 psig, one or both of the pressure relief valves open, thereby allowing air to initially escape. At this point, the fluid encapsulant from container 44 is continued to be introduced under pressure by pumping. Following the release of air through the valves 36, encapsulant sporadically escapes from one or both valves 36 until a steady stream of encapsulant flows from the valves. At this point, i.e. at 15 psig, the encapsulant is considered sufficiently pressurized to be forced around the cables, into the interstices between the cables, and around any connections in the splice. This thus creates a barrier against water migration throughout the interstices along the cable conductors. Once the steady flow of encapsulant is achieved, the splice enclosure is considered fully encapsulated and no air is present. Pumping of the encapsulant is then stopped, and the tube 42 is either severed or disconnected from the fitting 38. When the pumping is terminated, the flow of encapsulant from the valves 36 will likewise cease. Since the valves 36, as well as the fitting 38 are closed, the pressure will be maintained at approximately 15 psig over at least a period of time, e.g. two hours, which would allow the fluid encapsulant sufficient time to properly cure or set in order to establish the moisture barrier.

Closures 16 and 18 have pairs of matable longitudinally extending end surfaces, 16a, 16b and 18a, 18b as seen in Fig. 1. Longitudinal seamers 28 of generally circular cross-section are disposed between the end surfaces. Casting longitudinal grooves G16a, G16b and G18a, G18b and projections P16a, P16b and P18a, P18b cooperate with seam clamps 30 in the course of assembly, as is discussed in detail below, to sealably close the top and bottom closures.

Top closure 16 is provided with suitable openings 32 and 34 (Fig. 2) for respective receipt of two pressure-relief valves 36 and a fitting 38 for a pump 40 (Fig. 20), for purposes below discussed. Pump 40 (as seen in Fig. 20) also has an intake hose 42 for disposition directly in a bulk vessel 44 containing fluid encapsulant, i.e., as purchased from a supplier. The encapsulant is a two-part compound, comprising polyurethane, but other suitable encapsulants may be used. Each valve 36 has an inlet fitting for securement in a respective opening 32 of closure 16 and an outlet port 36a adapted for issuance of encapsulant from the assembled splice. Housings for the valves 36 and fitting 38 may be directly molded into the top closure 16, with valves 36 being oriented at an angle to allow fluid escaping therefrom to drip onto the top closure upper surface.

At least one of the end plate assemblies 20 and 22 defines a cable passage therethrough, e.g., where a spliced or tapped cable may be brought out through the same end plate assembly 20 or 22. In the illustrated embodiment, both of the end plate assemblies have such passages, for the splicing of conductors disposed in the end plate seals, e.g. seal 46 of Fig. 9, are disposed in the end plate assemblies.

By way of brief summary introduction to reaching the splice of the invention and kit 14, the method at hand involves the steps of outset preparation of the conductors to be spliced, i.e., connecting conductors and applying end plate assemblies 20 and 22 thereto, and the actual splicing, i.e., connecting the conductors with the use of conventional connectors, such as by crimping or other suitable hardware (not shown). End plate assembly seals 24 and 26 are applied to end plate assemblies 20 and 22 to encircle them and the top and bottom closures 16, 18 are juxtaposed with the end plate assembly seals and the longitudinal seamers 28 and closed thereon. Seam clamps 30 are applied as are clamps 48, in manner fully detailed below, to reach the splice stage as shown in Fig. 20.

At this juncture, with valves 36 in place, a funnel (not shown) is inserted in opening 34 of top closure 16 before the pump fitting 38 is attached. Encapsulant is poured therein directly from container 44 to a level substantially filling the assembly. Then, the funnel is removed and fitting 38 of pump 40 is secured into opening 34 and pump inlet hos 42 is disposed in container 44, where upon encapsulant fluid is

out of round or have some minor surface imperfec-
tions. The seals 46 are drawn up against respective
sealants 47. The seals are inserted into end plate as-
semblies 20 and 22, which have cable seals without
cable passages inserted into all cable receiving re-
cesses not passing cables therethrough. The com-
bination of the friction fit of opening 46g on the cable,
together with the sealant thereagainst, effectively
seals each cable to a seal 46.

Subsequent to the end plate assemblies 20 and
22, being joined to the cables, a bond bar 49 (Fig. 1)
is secured to the end plate assemblies 20 and 22. The
bond bar 49 is formed of conductive material, prefer-
ably metal, and is formed to have a predetermined
length. The longitudinal end portions of the bond bar
49 end are formed to have an opening for receipt of
any one of the bolts 70, 72, 74 or 76, projecting from
the rear wall 68c of each end plate. A threaded nut
96 secures the end portion of each bond bar 49 to a
respective end plate assembly 20 and 22 as depicted
in Fig. 1. Thus, a set axial dimension is established by
the predetermined length of the bond bar 49 between
the end plates 20 and 22 for proper location in the top
and bottom closures 16 and 18. Further, the bond bar
49 establishes a through-ground connection within
the splice which may be connected externally by any
one of the bolts 70-76 to which the bar 49 is connect-
ed, inasmuch as the bolts 70-76 extend outwardly of
the end plate assemblies 20 and 22. Further, the
bond bar 49 may be connected within the splice en-
closure to cable shielding by suitable hardware.

Seals 24 and 26 have been preferably disposed
in pre-assembly in the pockets 64 and 66 in the lower
closure 18, with the seamers 28a and 28b being lo-
cated in the longitudinal recesses 60 and 62. The end
plate assemblies 20 and 22 thus reached are nested
on the seals 24 and 26 in pockets 64 and 66. The
seals 24 and 26 are then locked on the end plate as-
semblies 20 and 22 by inserting locking members 24f
in receptors 24g.

Top closure 16 is now mated with bottom closure
18 nesting the upper recesses 52 and 54 on seamers
28a and 28b supported by bottom closure 18. Seam
clamps 30 are now applied to the assembly as above
discussed and shown in Fig. 19. Pockets 56 and 58
receive the upper halves of end plate assemblies 20
and 22 with the locked seals 24 and 26 circumferen-
tially thereon.

Clamps 48 (Fig. 20) which are preferably metal
band clamps with a locking screw are now applied
about the joined top and bottom closures and tight-
ened. In the course of tightening of the clamps, vari-
ous seals are enhanced. Top and bottom closures 16
and 18 are forced into tight, moisture-resistant en-
gagement with longitudinal seamers 28a and 28b.
The walls of pockets 56 and 64 and of pockets 58 and
66 bear down respectively on the seals 24 and 26 on
the end plate assemblies 20 and 22 providing tight,

6

an opening for the locking member, the interfitting of
the locking member in the receptor providing secure-
ment of seal 24 about the periphery of end plate as-
sembly 20. Sealing ribs 24h and 24i extend longitudin-
ally along the surface 24c of seal 24.

The perspective partial view of Fig. 16 depicts
the disposition of seal 24 within bottom closure 18. As
is seen therein, protruding sleeve 24d is situated in
pocket end portion 64b of closure 18 and seal 24 is
otherwise disposed in pocket 64, with the end extent
of longitudinal seamer 28b adhesively secured in pro-
truding sleeve 24d. In a preferred arrangement, the
assembly seals 24 and 26, together with both longi-
tudinal seamers 28a and 28b, are formed integrally as
a one-piece, molded member adhesively attached to
the lower closure 18 in a pre-assembly.

Turning to Figs. 17 and 18, longitudinal seam
clamp 30 is a rigid member, preferably constituted of
metal, and defines a channel 30a formed by inclined
legs 30b and 30c projecting from a central interior flat
section 30d. Legs 30b and 30c are configured com-
partially with projections, P16a, P16b and P18a P18b,
above discussed, for nesting of the projections in the
channel 30a. End wings 30e and 30f are likewise con-
figured compatibly with grooves G16a, G16b and
G18a, G18b, also above discussed, for residence
therein.

Fig. 19 is illustrative of a partial section (material
section being omitted) of a splice enclosure in ac-
cordance with the invention. Top closure 16 and bot-
tom closure 18 have their matable end surfaces 16a
and 18b in juxtaposition. Longitudinal seamer-receiv-
ing recess 52 of top closure 16 and the counterpart
seamer-receiving recess 62 of bottom closure 18 will
bear on seamer 28b, which will also be seen to be pre-
ferably a solid rubber cylinder. Legs 30b and 30c of
seam clamp 30 are resident respectively in grooves
G16a and G18b and bear upon its angled sidewalls
that, together with inclined legs 30b and 30c,
squeeze the top closure 16 and the bottom closure 18
tightly on seamer 28b.

Thus, the method of the present invention in-
volves the following steps. Cable seals 46 are select-
ed such that openings 46g are compatibly sized with
the diameter of cables 10 and 12. Seals 46 may be
formed without existing cable passages, but with di-
verse diameter circular indications on a full central
panel thereof. The seal central panel is then cut as
desired to define the desired cable passage of size to
receive the cable in frictional fit. Cables 10 and 12 are
now inserted into the cable seal openings 46g. To
compensate for any unevenness of the slit 46m in the
seal body portion, a small section of butyl-type tape
may be placed in the slit 46m after the cable is insert-
ed. A sealant 47 (see Fig. 1) in the form of pliable tape,
such as a butyl-type tape is applied around cable jack-
ets 10a and 12a. This sealant 47 provides compensa-
tion for imperfect cable jacket surfaces, which may be

55

5

of to penetrate the insulation of cable jackets passing through base plate 68' under the influence of a clamp 110 as shown in Fig. 23 applied circumscriptively to support 98 with one or more cables in place.

Advantage attending the use of the structure of Figs. 21-23 is principally in displacing the location at which cables will bend under abuse distal from the location at which the cables exit the cable seals. Secondary benefit is the resistance to longitudinal movement of the cables relative to the cable seals, i.e., longitudinal strain-relief.

While the support 98 may be located outwardly of the splice enclosure, the preferred arrangement of the invention contemplates the provision of such support extending from the base plates 68' inwardly into the splice enclosure, and thus also encapsulated, to provide for enhanced longitudinal strain relief within the splice assembly.

Various modifications to the particularly illustrated splice and sealing structure of the invention may evidently be introduced without departing from the invention. By way of example, it will be appreciated that the sealing structure has utility also in the second above-noted approach to splice protection. Thus, it is to be understood that the specifically disclosed and depicted embodiments are intended in an illustrative and not in a limiting sense. The true scope of the invention is set forth in the following claims.

Claims

1. A cable splice, comprising:
A. first and second elongate casings juxtaposed along respective end surfaces thereof to define a housing with an open interior;
B. at least one electrical cable disposed in the housing interior in a pressurized encapsulant, the encapsulant filling the housing interior;
C. at least one end closure means disposed in said housing and defining a cable passage therethrough, a portion of said cable being sealably resident in said cable passage; and
D. seal-effecting means for providing sealed relations between said first and second casings, between said end closure means and said end plate means and said cable portion, said seal-effecting means being inclusive of said movable means for selective longitudinal movement in confronting relation to said end closure means.
2. A cable splice as claimed in claim 1, wherein said seal-effecting means includes first and second elongate sealing members, said casings including a recess therein, pairs of juxtaposed such re-

moisture-resistant circumferential engagement between such walls and seals 24 and 26 and between seals 24 and 26 and the circumference of the end plate assemblies 20 and 22. Further, the ears 46d and 46e of cable seals 46 are forced radially inwardly, with resulting tight, moisture-resistant engagement with the end plate ledgers 78b and 78c.

As will be recalled, cable seals 46 are configured to extend axially outwardly of the front wall 68b of base plate 68 and recesses 88-94 are so dimensioned that cover plate 86 has expanses confronting the cable seals. A further step in the assembly is to now tighten nuts 96 onto bolts 70-76 of each of end plate assemblies 20 and 22. This results in a forcing of cover plates 86 toward base plates 68 commonly compressing the cable seals 46 such that the bodies 46f of the seals are forced against the internal walls 78a. Thus, sealing is effected between the cable seals 46 and the internal wall 78a and also between the cable seals 46 and the cover plate 86 along the periphery of the front wall 68b adjacent the U-shaped surface 78d. Sealing of the cables to the seals, as described hereinabove, is effected by the frictional force of the cable opening 46g and the sealant 47 pressed thereagainst. Although some sealing may occur between the seal body portion 46f and the sealing surface 78d under the influence of the clamps 48, this is considered insufficient for this application, the effective seal of the seal body portions to the base plate 68 occurring under the influence of the axial movement of the cover plate 86 thereagainst.

The described protective closure is readied for the outset funnel introduction of encapsulant and subsequent pressurized introduction of encapsulant through fitting 18 by pump 40, as in Fig. 20. In Fig. 20(a), a perspective view is seen of the finalized splice assembly of the invention with components other than bottom closure 18 removed for purposes of illustration of the set, pressurized encapsulant E having shape conformity with the interior of closure 16, i.e., fully semi-cylindrical with cables 10 and 12 embedded therein and protected against moisture intrusion.

Turning to Figs. 21-23, a further version of base plate 68 is indicated as 68'. Cable support 98 extends outwardly of base plate 68' and is preferably formed integral with the base plate, i.e., is molded therewith. Support 98 has four cable rests, one being shown at 98a, each in the form of a semicylindrical depression in support 98 and in registry with recesses 100, 102, 104 and 106.

A strain-relief member 108 comprises four arcuate portions 108a-d which nest respectively in the cable rests 98a of support 98. Each arcuate member 108a-d is suitably secured to the support 98, for example, by a tab 108e-h which, for example, may be attached to the support 98 by screws or rivets. The arcuate portions have teeth 108i struck outwardly there-

- cesses being complementarily configured for respective receipt of said first and second elongate sealing members.
3. A cable splice as claimed in claim 1 or claim 2 wherein said end closure means comprises a base plate having at least one cable seal-receiving recess extending inwardly from the periphery of said cover plate in registry with said cable seal-receiving recess of said base plate, said movable means comprising a cover plate mounted on said base plate for movement relative thereto, said cover plate defining a recess extending inwardly from the periphery of said cover plate in registry with said cable seal-receiving recess of said base plate.
4. A cable splice as claimed in claim 3, wherein said seal-effecting means includes at least one cable seal configured compatibly with said cable seal-receiving recess of said base plate and resident therein, said cable seal defining said cable passage.
5. A cable splice as claimed in claim 4, wherein said recess of said cover plate is of lesser dimension than said cable seal-receiving recess of said base plate, whereby said cover plate has expense in confronting relation with said cable seal.
6. A cable splice as claimed in claim 5 wherein said seal-effecting means includes seal-implementing means for maintaining said cover plate expense in force-applying relation with said cable seal.
7. A cable splice as claimed in claim 2 wherein said seal-effecting means further includes a sealing element encircling said end closure means, said casing defining interior pockets of said sealing element having sleeve means, end extents of said first and second elongate sealing members being resident in said sleeve means.
8. A cable splice as claimed in any one of claims 1 to 7 further including:
- E. cable-engaging means adapted to displace the location of bendability of said cable to a location distal from said cable passage.
9. A cable splice as claimed in claim 8, further including:
- F. strain-relief means adapted to resist longitudinally imposed strain applied to said cable.
10. A cable splice as claimed in claim 9, wherein said end closure means comprises a base plate having at least one cable seal-receiving recess extending inwardly from the periphery of said base plate.
11. A cable splice as claimed in claim 10, wherein said cable-engaging means is in part integral with said cover plate.
12. A cable splice as claimed in any one of claims 1 to 11, further including:
- G. at least one pressure-relief valve having an inlet fitting secured in said housing opening and an outlet port adapted for issuance therefrom of encapsulant applied into said housing open interior.

⑥ Moisture-resistant cable splice and sealing structure thereof.

⑥ A protective enclosure for use with one or more electric cables (10, 12) comprises first and second elongate casings (18, 18) juxtaposed along respective end surfaces thereof to define a housing with an open interior, at least one electrical cable (10, 12) disposed in the housing interior in an encapsulating filling the housing interior. At least one end closure (20, 22) is disposed in the housing and defines a cable passage therethrough, the cable being resident in part in the cable passage. Seal-effecting structures for providing sealed relations (16a, 16b, 18a, 18b, 28) between first and second casings (24, 26), between the end closure and the first and second casings and (46) between the end closure and the cable part is inclusive of a cover plate disposed in confronting relation to the end closure and movable relative thereto.
